FOREWORD
by
F. Kalil

This report is the second in a series of reports to be presented by the Applied Physics Laboratory (Contract NOw 62-0604-C, Task N), regarding the reliability of the Manned Space Flight Network (MSFN). The reliability analyses contained herein are based primarily on failures experienced during flight support status. Previous analyses and predictions of MSFN reliability for supporting the lunar orbiting mission (Apollo 8, AS-503) were reported[1] prior to the mission. These latter predictions correlated with the actual experience during the AS-503 mission. This report presents similar predictions about the MSFN reliability for supporting the forthcoming lunar landing, which is scheduled for July, 1969. The reliability predictions contained herein differ from the previous ones[1] in that these predictions: (1) incorporate data from a larger number of missions; and (2) consider the fact that two manned vehicles must be supported simultaneously during the phases when the LEM descends, lands and stays on the lunar surface, ascends, and docks with the CSM. These phases put the MSFN to a more severe use; however, the predictions herein indicate that the MSFN will be able to successfully support the mission. Although the reliability predictions are contained in the body of the report, they are repeated here in summary form (Tables I and II) for completeness and emphasis. The mission phases referred to in Tables I and II are diagrammatically depicted in the following Figure-a.

As shown in Tables I and II, the MSFN's reliability is predicted to be ~0.999 for each of the support functions during each phase of a lunar landing mission. Redundancy in both hardware and mission coverage were considered, and all failures (hardware, software, and operator) were considered. The single site availability is predicted to be ~0.86 on the average for each of the support functions listed for the earth orbital phases; however, the availability for each of the functions approaches ~0.997 shortly after translunar injection when three or more stations are in view of the spacecraft. It should be noted that the availability of ~0.86 for a single site could be misleading, primarily because not each site must necessarily support every function in the earth orbital phase to insure success of the mission. For instance, MIL, GBM, and GBI provide redundant coverage during the launch phase; and the network provides 17 contacts, about 7.5 minutes each, via individual stations during the first two orbits of the earth packing orbit phase for check-out of the spacecraft systems.

LUNAR LANDING MISSION RELIABILITY STUDY

1. Introduction

A study has been done to estimate the mission support function reliability of the Manned Space Flight Network for a lunar landing mission. This is a follow up effort to a previous study done for a lunar orbital mission. The lunar orbital mission study was submitted to the Manned Flight Planning and Analysis Division (MFPAD) at Goddard Space Flight Center in early December, 1968. The lunar orbital mission study was also included in the October-December 1968 Quarterly Progress Report of the Manned Space Flight Network Study Program (Reference 1). This is the quarterly progress report by the Space Communications Group (CSC) of the Johns Hopkins University/Applied Physics Laboratory.

The present study extends previous work in several areas:

(1) A more complex mission profile is considered with additional mission phases such as "transposition and docking," "lunar module descent and landing" included. The most significant additional complexity, from a MSFN reliability standpoint, is that during much of the mission, coverage must be provided for two spacecraft.

(2) Failure and repair data for 5 missions has been utilized in compiling the reliability estimates. This data has been obtained from NOM and MMR mission status reporting for the AS-501, AS-204, AS-502, AS-503, and AS-205 missions. The last two listed missions provided data not available for the previous study. For the AS-503 and AS-205 missions it was necessary to reduce the data directly from the station submitted TWX reports since no post mission problem summaries were provided as had been done for the three earlier missions.

(3) A summary tabulation of "Availability" is included in addition to summary and detailed tabulations of "Reliability." This is done to estimate, under certain assumptions, the effect of site down time. A discussion of the interpretation of "Availability," how it differs from "Reliability," and the assumptions made in determining the estimates is given in Sections (2) and (3).

Equipment failure data was translated into functional support reliability estimation by interconnecting, from a reliability standpoint, those equipments necessary for the support of the function assumed. Equipment redundancy and multiple site coverage were taken into account.

2. Summary of Results

Table I is a summary tabulation of site mean time between failure (MTBF) and overall Reliability via multiple site coverage for the four major MSFN support functions during each phase of the mission. Table IV is a more detailed tabulation of the same information with major support functions broken down into subfunctions.

The list of required support functions assumed for this study is given in Figure 1. The tables show that no functional MTBF, as estimated from the data, is less than 107 hours for a single site.

The reliability estimates are obtained from the MTBF estimate, an exponential failure law assumption, and a weighted combination of the site coverage time interval and number of sites covering depending upon mission phase. These reliability estimates give the probability of failure free support over a time interval by at least one site out of the total number of covering sites. The coverage time interval and number of sites covering depend upon mission phase.

Table II is a summary table of single site and multiple site coverage Availability for the four major MSFN support functions. These estimates are approximations which take into account the ratio of average repair time to mean time between failure for each equipment area and the amount of equipment required to support each function. The interpretation of these availability estimates differs from that of reliability in that reliability is a time dependent probability of failure free operation given that the time interval began with the site in the "up" state. Availability is an asymptotic or "steady state" probability of being in the "up" state after some time has passed and does not depend upon the state of things at the beginning of the time interval if a sufficiently long time interval is considered. This asymptotic probability (availability) is reached after a period of time has passed during which both failures and repairs have occurred. The estimates can be interpreted as measuring the probability of, at any arbitrary time during the mission, finding a site (or at least one of 3 sites) capable of supporting the function.

The estimates of reliability and availability can both be of interest from different viewpoints. Reliability is of more concern when a relatively short interval of time is considered during which it is essential that no failures occur. Availability is of more concern when a longer period of time has passed over which it is likely that failures (and hopefully rapidly completed repairs) have occurred and the probability of finding a site "up" is considered.

*Two spacecraft

I Determine Position of Spacecraft vs Time (Tracking/Navigation)
- A) Receive Position/Time Data from MCC or MSFN
- B) Acquire and Track Spacecraft and its Signals
- C) Transmit Spacecraft Position/Time to MCC
- D) Record Spacecraft Position/Time at Site

II Maintain Voice Communications with Spacecraft
- A) Receive voice from MCC
- B) Transmit voice to spacecraft
- C) Receive voice from spacecraft
- D) Transmit voice to MCC
- E) Record voice on site

III Monitor Spacecraft Status and Systems
- A) Receive telemetry from spacecraft
- B) Process and transmit telemetry summaries to MCC
- C) Record telemetry on site
- D) Receive Television from spacecraft

IV Send Commands/other Up Data to Spacecraft
- A) Receive commands MCC
- B) Process command data
- C) Transmit up data to spacecraft
- D) Verify that up data is transmitted
- E) Verify that up data is received
- F) Transmit command verification to MCC
- G) Record command history on site

V Maintain Site Proficiency
- A) Test and maintain systems performance
- B) Maintain voice communication with MCC and MSFN
- C) Maintain teletype communication with MCC and MSFN
- D) Maintain data communication with MCC and MSFN
- E) Monitor and maintain all fundamental power equipment
- F) Receive and originate documents and reports

Figure 1–List of Mission Support Functions for each MSFN Site

3. Outline of Data Analysis

The following material summarizes how the basic data available for this study was reduced and utilized.

(a) All failures and their associated down times reported during the five mission status periods were categorized into appropriate MSFN site equipment areas. The equipment category breakdown list has been presented in previous documents[1] and is not attached to this study.

(b) Mean time between failure (MTBF) estimates, taking down time into account, were calculated via computer programming for each equipment area. Down times for each equipment area were also tabulated.

Failure and down time data for certain equipment areas obtained over all five mission status periods is presented in histogram form in Appendix I. This data is representative of data used in the study.

(c) By interconnecting the equipment areas (or "subsystems") as required for each support function of Figure 1 a functional reliability estimate for a site is obtained from the MTBF estimates of each equipment area and the time interval of site coverage for each mission phase.

An "overall" MTBF estimate for each function is also obtained by combining the estimates for each equipment area. The functional reliability estimates and overall MTBF estimate are not related in a simple exponential way since both series and parallel (redundant) equipment interconnections are involved and the resulting distribution of failure times is no longer exponential. In a redundancy situation for a failure to have occurred, all parallel paths must have failed. Table III presents the basic single site reliability data analysis for each support function. This table gives the single site reliabilities for each support function as calculated from the data for selected time intervals applicable to this study. All subsequent estimates of support reliability are based on Table III.

(d) By considering total MSFN coverage, i.e., the number of sites which can view the spacecraft(s) during any given mission phase, an overall MSFN support function reliability estimate is obtained. In this situation "redundancy" is provided by the number of sites covering. This

---

[1] For example, the Lunar Orbital Mission Reliability Study included in the October-December 1968, APL quarterly progress report mentioned in the introduction.

F	.99945	.99593	.99188	.96795	.93695
G	.99942	.99574	.99151	.96648	.93013

"redundancy" varies depending upon whether one or two spacecraft are covered. From a reliability standpoint it is found that dual sites provide very little redundancy when a single spacecraft is considered. A summary of site coverage for a lunar mission is given in Figure 2. The detailed information from which the summary of Figure 2 was obtained is included in reference 1. This reference described in detail coverage for a night launch in August 1969 involving translunar injection over the Atlantic. The first lunar landing mission may well occur in July 1969 with translunar injection over the Pacific. These missions would differ in detail as to which sites covered when, but the overall summary of coverage as given in Figure 2 should apply to either.

A summary table of site mode support capability is given in Figure 4. It has been assumed in this study that 30 ft antenna sites can "back up" 85 ft antenna sites at lunar distance in the PM modes. (Contingency" modes or modes other than mode 2 might have to be used.) The 30 ft. antenna sites cannot "back up" the 85 ft. antenna sites at lunar distance in the FM modes which includes television. These assumptions can be inferred from Figure 4. Examples of the variation in equipment redundancy for certain USB areas as a function of site coverage is shown in Figure 3. Implications for other on site equipment existing in the same quantities as those selected for illustration can be obtained from Figure 3.

(e) In estimating "availability" the ratio of average down time to mean time between failure can be used when both the failure times and repair times are exponentially distributed;

$$A \approx 1 - \frac{MTR}{MTBF} + \left(\frac{MTR}{MTBF}\right)^2$$

For this study availability estimates were obtained using average down times for each equipment area but including only those repairs completed within 30 hours in calculating the average down time. The histogram examples of down time data given in Appendix I show a "bi model" or even "multi model" distribution of down times. Much of this is due to "logistics time" during mission status contributing to down times as long as two weeks or so. Such lengthy down times are assumed not to be typical of mission flight periods. It is assumed that every effort would be made during pre launch mission status to provide necessary spares and if needed, replacement could be flown to sites relatively quickly while a mission is in progress.

If "logistics down times" are not considered the data indicates that in most equipment areas most failures are repaired within one day with a typical average down time of about 8 hours.

LUNAR LANDING MISSION REI

...LIST FIG. 1

...AIN SITE PROFICIENCY) IS ASSUMED TO BE THE REQUIRED SUPPORT FUNCTION.

1.) Launch, Earth Parking Orbit
   a) Coverage (Discontinuous)
      Minimum number of sites, one, 85 ft or 30 ft antenna
      Typical number of sites, two or more in certain regions
   b) Typical time interval of coverage by one site, 8 minutes

2.) Translunar Injection (TLI)
   a) Coverage (Continuous)
      Minimum number of sites, two 30 ft antenna dual sites, (one a ship)
      Typical number of sites after TLI, one 85 ft site and wing site, three 30 ft antenna dual sites (one a ship)
   b) Typical time interval of coverage by one site, TLI approx. 5 minutes, 9 hours following TLI

3.) Transposition and Docking, S4-B Separation (T and D)
   a) Coverage (Continuous)
      Minimum number of sites, one 85 ft antenna site with wing site, three 30 ft antenna dual sites (one a ship)
      Typical number of sites, same as above for about 4 hours after transposition and docking, then additional coverage available
   b) Typical time interval of coverage by one site, T and D approx. 2 hours, 7 hours following T and D

4.) Translunar Flight
   a) Coverage (Continuous)
      Minimum number of sites, one 85 ft antenna site and wing site, two 30 ft antenna dual sites
      Typical number of sites, one 85 ft antenna site and wing site, two 30 ft antenna dual sites, and two 30 ft antenna single sites
      Maximum number of sites, two 85 ft antenna sites and wing sites, two 30 ft antenna dual sites, and six 30 ft antenna single sites
   b) Typical time interval of coverage by one site, 12 hours
      (Over a 12 hour interval the continuous coverage will be by the minimum number of sites for approximately 2 hours, the typical number for approximately 8 hours, and the maximum number for approximately 2 hours)

Figure 2–Approximate Summary of MSFN Coverage for a Lunar Mission

PAGE 22 BLANK

5.) Prior to Lunar Orbit Insertion
   a) Coverage (Continuous)
      Typical number of sites, one 85 ft antenna site with wing site, three 30 ft antenna dual sites
   b) Typical time interval of coverage by one site, 3 to 9 hours prior to lunar occultation

6.) Lunar Orbit by CSM, Lunar Stay by LM
   a) Coverage (Continuous for LM, discontinuous for CSM due to lunar occultation)
      Minimum number of sites, one 85 ft antenna site and wing site, two 30 ft antenna dual sites
      Typical number of sites, one 85 ft antenna site and wing site, two 30 ft antenna dual sites and two 30 ft antenna single sites,
      Maximum number of sites, two 85 ft antenna sites and wing sites, two 30 ft antenna dual sites, and six 30 ft antenna single sites
   b) Typical time interval of coverage by one site
      i) For LM, 12 hours
      ii) For CSM, 1.2 hours on, 0.8 hours off due to lunar occultation (As for the translunar and transearth phases, over a 12 hour interval the continuous coverage will be by the minimum number of sites for approximately 2 hours, the typical number for approximately 8 hours, and the maximum number for approximately 2 hours)

7.) LM Touchdown on Lunar Surface, LM Ascent and Prior to Rendezvous
   a) Coverage (Continuous)
      Maximum number of sites, two 85 ft antenna sites and wing sites, three 30 ft antenna dual sites, two 30 ft antenna single sites
   b) Typical time interval of coverage by one site,
      Approx. 1 hour during LM descent including lunar touchdown, 10 hours following lunar touchdown
      Approx. 1 hour following LM ascent to lunar occultation

8.) Prior to Transearth Injection
   a) Coverage (Discontinuous)
      Typical number of sites, one 85 ft antenna site and wing site, two 30 ft antenna dual sites, and four 30 ft antenna single sites
   b) Typical time interval of coverage by one site,
      Approx. 1 hour prior to lunar occultation

Figure 2 (continued)–Approximate Summary of MSFN Coverage for a Lunar Mission

9.) Transearth Flight
   a) Coverage (Continuous)
      Same as for translunar flight
   b) Time interval of coverage by one site
      Same as for translunar flight

10.) Entry
   a) Coverage (Discontinuous)
      Typical number of sites, one 30 ft antenna site, single or dual
   b) Typical time interval of civerage by one site, approx. 5 minutes

Figure 2 (continued)–Approximate Summary of MSFN Coverage for a Lunar Mission

One Spacecraft Coverage by:	20 MHz Local Oscillators per Spacecraft	Reference Loops per Spacecraft	Ranging Systems per Spacecraft	TLM Receivers per Spacecraft	Antennas* per Spacecraft	
					PM Modes	FM Modes
1 85 ft antenna site and wing site, 1 30 ft antenna dual site	6	12	6	12	3	2
1 85 ft antenna site and wing site, 2 30 ft antenna dual sites, 2 30 ft antenna single sites	10	20	10	20	6	2
2 85 ft antenna sites and wing sites, 2 30 ft antenna dual sites, 6 30 ft antenna single sites	18	36	18	36	12	4
Two Spacecraft Coverage by:						
1 85 ft antenna site and wing site, 1 30 ft antenna dual site	3	6	3	6	1.5	1
1 85 ft antenna site and wing site, 2 30 ft antenna dual sites, 2 30 ft antenna single sites	5	10	5	10	3	1
2 85 ft antenna sites and wing sites, 2 30 ft antenna dual sites, 6 30 ft antenna single sites	9	18	9	18	12	2

√ = adequate signal margin, mode can be supported
√? = no signal margin, mode degraded but could probably be supported
X = mode cannot be supported

Margins are based on a TLM signal to noise ratio for 10^{-6} bit error probability, voice signal to noise ratio of 10 db for 90% word intelligibility and a PRN ranging signal to noise ratio of 0 db for 1 minute of integration.

Figure 4–Representative Mode Support for the Unified S-Band System with Adequate Signal Margin for Nominal MSFN and Spacecraft Parameters

APPENDIX I

This appendix contains histograms of the total number (over the five missions status periods) of reported failures and repair times for some of the on site equipment categories. Included specifically are the Unified S-Band and 642-B computer areas.
